INTRODUCTION

The present work containing the Indian scientific names of our entire avifauna is one of the several volumes that constitute the Great English-Indian Dictionary.

India, Burma and Ceylon contain one of the richest and most varied avifaunas on the face of the globe. Covering some 40 degrees of latitude and about the same of longitude, they enclose within their boundaries a vast diversity of climate and physical features. These range from the dry, scorching sandy deserts of Sindh and Rajputana and the humid ever-green rain forests of Assam and the South Western Ghats, to the region of glaciers and eternal snow in the mighty Himalayas. Smooth wide spaces of depressed river basins, either sandy, dry and sun-scorched or cultivated, or water-logged under a steamy moisture-laden atmosphere (the terai) lie at the base of the northern ramparts. The great Central Indian and Deccan Plateaux succeed the fertile alluvial Gangetic Plain and are flanked on the west by the broken crags and castellated outlines of the ridges of the Western Ghats which overlook the Arabian Sea and continue southward in gentle, smoothly-round-

ed slopes of green uplands—the Nilgiri and other hills of Southern India.

Altogether there are 24 hundred species and subspecies which have been described with great patience and scholarship by E. C. Stuart Baker in the 8 volumes of Indian Fauna (Birds). They were published from July 1922 to September 1930. Each bird has been given a bi- or a tri-nomial designation. According to the scientific practice in the West the names are in Latin. Each Latin name is followed by an English name. The English names are not always translations of Latin.*

*Trinomial names are sometimes rendered by binomials—

Lat.—*Brachy-pteryx major albi-ventris*.

Eng.—*The White-bellied Short-wing*.

Here *major* is left out. The rest is faithfully rendered.

Proper names of places and persons are freely replaced. There is no sacrosanctity about them—

Lat.—*Cinclus pallassii tenuirostris*.

Eng.—*The Indian Brown Dipper*.

Lat.—*Tickellia hodgsoni*.

Eng.—*The Broad-billed Flycatcher-Warbler*.

Lat.—*Acrocephalus concinens stevensi*.

Eng.—*The Plains Paddy-field Warbler*.

This Reed-Warbler was discovered breeding by Mr. and Mrs. H. Stevens in Lakhimpur, but while translating in English it was not considered necessary to retain the discoverer's name.

In the Latin nomenclature the words signifying the genus come first and those signifying the sub-species come last, the words for the species being placed in between. In English the order has been reversed, the sub-species coming first and the genus coming last.

Binomial or trinomial system of naming plants and animals is a recent scientific device. In ancient times we have single names standing mostly for species. Our ancestors lived with nature and loved plants, animals, rivers and mountains. They observed and named animals with loving care. We find hundreds of names of birds in Sanskrit literature. The variety and number of Sanskrit names is often baffling. It is not possible to identify every bird mentioned in Sanskrit literature. Shri K. N. Dave has been at the problem for sometime past and has worked out probable identifications. His work entitled 'Birds in Sanskrit Literature' would be published shortly as a separate volume. A sample chapter on Paroquets or Parrots is appended to the Introduction.

In the present work ancient names have been fitted into the trinomial scientific scheme. These names, while serving the needs of scientific classification would be found to be more significant, easier to grasp, simpler to pronounce and hence uncomparably quicker

to remember than their Latin counterparts. In certain quarters it has sometimes been felt that Latin names be left untranslated. But this view loses all force when we find that foreigners who came to India from a distance of six thousand miles thought it practicable to append to every Latin name an English trinomial designation so that their compatriots could better study and appreciate Indian birds than could ever be done through the mouth-filling mass of vowels and consonants known as scientific names. The Indian names, moreover, correlate the present with the past. Our names have a pedigree and hence future scientific studies will not be removed from the past achievements of the race. It does not, however, mean that Indian scientists will not acquire a knowledge of Latin names. Research workers will have to get acquainted with Latin and English names when they are studying the works written by foreign scholars.

Sanskrit words are a fascinating study. Sanskrit is known for being the most transparent language. Seven or eight words out of ten are crystal clear in the basic idea on which they have been founded. They embody the observations and the reactions of our forefathers to their surroundings.

The general word for a bird is पक्षिन् 'feathered'.

Birds are conspicuously different from all other classes in that they possess feathers. This idea of a feathered creature was constantly before the mind's eye and hence besides पक्षिन् we have such other words as पक्षधर and पक्षालु. It was further extended to पक्षगम 'going with the help of feathers' and पक्षवाहन 'having feathers as the vehicle'. पत्र, the parent of English 'feather', and पतत्र, both from पत् 'to fly', and signifying 'feather' have yielded some more synonyms—पत्रिन्, पत्र-वाह, पत्रिवाह, पत्र-रथ and पतत्रिन्.

Another designation of birds is द्विपाद 'biped'. अंडज 'oviparous', द्विज 'born twice—once the egg and then the young one from the egg', द्विजाति, अनेकज were constantly used to signify a bird. But this characteristic is not an exclusive one. It is shared by birds with reptiles and other creatures.

तपस 'warm' is a curious epithet for a bird. Of course we know that the temperature of the body of a bird is 2 to 14 degrees higher than that of mammals. The high temperature is connected with the large proportion of muscle, and the conservation of heat is secured by the nonconducting plumage.

शकुन or its synonyms शकुन्त, शकुनक, शकुनि, शकुन्ति are derived from the root शक् 'to be strong', the root from which we get the common words शक्ति 'power'

and शक्र Indra 'the mighty'. One of the Vedic words for bird is वाजिन् 'powerful' from वाज 'strength'. These are highly expressive of the great invigoration of life which is contributed to birds by a supply of purely arterial blood pumped by the four-chambered heart.

With flight is connected the more lightly built skeleton, the sternum acquiring a keel for the insertion of the muscles of flight, the neck becoming long and supple and the beak taking on the work of a hand. This is beautifully expressed by the Sanskrit term त्रोटकहस्त (त्रोटक 'beak', हस्त 'hand').

नीडज, नीडोद्भव 'born in a nest', नीडिन् 'having a nest', वृक्षगृह, वृक्षावास, अगौकस्, नगौकस् 'making their homes in trees', तरुशायिन् 'resting on trees' and again कुलायस्थ 'nest-dweller' are popular epithets and are used as regular synonyms of पाक्षिन्.

Insects, bats, birds and the extinct Pterodactyls in which a fold of skin was extended on the greatly elongated outermost or fifth finger, are all included in the term पतंग 'which move by flying'.

वा 'to blow' gives वायु, वात for 'wind' and a series of words for 'bird' वि, वी, वीक, वे, वयस्, वयस, वाय, वायस. From वि is derived the Sanskrit word for aerial car विमान 'made to the measure of birds'. The wings of birds combine the functions of propellers and planes.

The value of flight is obvious but it may be useful to recall some of the different ways in which it has justified itself in the struggle of existence. It gives its possessor a new safety and independence, expressed in the Sanskrit word यथेष्टचारिन्. It enables them to follow food and to seek water over long distances. It helps them to secure the well-being of their offspring by building nests in places often inaccessible except to enemies able to fly or climb. The power of flight has given to birds a unique power of annihilating distance, of evading the winter, of having two summers in the year, of having two homes, of changing their season in a night. In seeking out suitable feeding-places and breeding-places neither space nor time present obstacles to the flying bird.

Teeth are absent in modern birds. The Sanskrit poet has alluded to this feature by रसना-रद. Their absence is compensated for by the horny bill covering the jaws अस्थितुण्ड, कीकस-मुख, कीकसास्य (अस्थि- and कीकस- both signify 'bony'). It often has a sharp edge and a hooked tip; it varies from a massive crushing instrument in the toucan to a delicate probe in the humming bird. The variety of type should be considered in the light of the fact that the forelimb has been surrendered to making a wing, and that the bird's jaws have to discharge duties

which in mammals usually fall to the hands. Hence the name चोटक-हस्त referred to before. It would be profitable to pursue a paragraph or two to realise the value of the bill as a hand.

A generalized bill may be illustrated by the crow and its allies—strong pointed, somewhat triangular in section. Shortening, sharpening and curving of such a bill would yield the predatory type of hawk and eagle—quick to give the death-blow by piercing the skull or cutting the jugular vein, also well suited for rapid skinning and plucking, and for drawing out strips of flesh from the body. It is interesting to see an eagle deftly run down the backbone of a fish with its bill, dislocating the vertebrae. Somewhat of the same type are the bills of the owls and the parrots, though the former are carnivorous and the latter vegetarian. The parrot's beak has a movable hinge between the premaxillae and the front of the skull, and there are often strong file-like roughnesses to the inside of the bill, which serve in gnawing nuts or grinding hard seeds. Not very remote are the broadly conical strong bills characteristic of the finches, suited for breaking capsules and splitting seeds.

On another line are the delicate slender types, familiar in warblers, suited for dealing with small insects, with a climax in the elongated slender bills of

humming birds. Not far removed, though used in a different way, are the elongated narrow bills of curlews, snipe, avocet and woodcock, for probing in mud, sand and the like. In a very different direction are the broad bills of ducks and geese, for sifting the mud and cropping vegetation, and on this line might be placed the broad bills of some storks and herons, and the spatulate type of the spoonbill. Also broadened out, but kept very short, are the insect-catching bills of nightjar and swift. A slight specialization of the rook-type leads to the sharp form of bill seen in snake-birds, herons and bitterns. Lateral compression in puffin and razor-bill reaches an extreme in the long, high knife-blade of the skimmer (*Rhynchops*), a tropical relative of the terns. This bird flies very close to the surface and skins the water with the mandible which is longer than the upper jaw. When the knife edge of the mandible touches a small fish or crustacean it tilts the booty into the open mouth. The skimmer or scissor-bill is also said to skim soft mud. There are many strange types, such as that of the crossbill, where the points of the upper and lower halves of the beak cross one another when at rest, a position that occurs as an abnormality in some birds, such as crows. The peculiarity is utilized by the crossbill in the exceedingly rapid extraction of the seeds of fir-cones, a deft manipulation in which the tongue

assists. In the wry-bill plover of New Zealand the bill is turned to the right-hand side, and it is interesting to notice that a one-sided twist is occasionally seen in an individual oyster-catcher. In the flamingo the whole beak is bent almost at right angles on itself, half-way down its length, and is thrust upside down into the mud, where it searches for small molluscs and the like. The kiwi is the only bird in which the nostrils open at the tip of the bill. In the huia, another New Zealand rarity, there is sex-dimorphism in the bill. According to Alfred Newton, the male uses his short, strong, almost straight bill to chisel holes in decaying wood where grubs may lurk, while the female uses her much longer, decurved and slender bill to probe into crevices. But when he, having discovered a grub in his excavations, is unable to reach it, she utilizes the opportunity.

अंगु and अंजस् (from अंज्, उणादि) imply intensity of motion. Going through the sky is a pet name of the Sanskrit poets and is expressed in various ways ख-ग (ख sky), खगम, खचर, खेचर, विहग, विहायस्, विहायस, विहंगम, विहग, विहंगक, द्युग (द्यु sky), द्योभूमि 'for whom the sky is the earth', नभश्चर, नभसंगम, अम्बरचर, उपरिचर, अभ्रग 'going among the clouds', गगनचर, गगनेचर, व्योमचारिन्, अन्तरिक्षग, अन्तरिक्षचर, आकाशचारिन्, आकाशग, वियच्चारिन्.

वातगामिन् 'going with the wind' is a significant

designation. Besides ordinary flight, there is gliding—when the bird, having attained to a certain velocity, rests on its oars for a while; or having attained a certain height descends to the ground without any stroke of its wings.

चातगामिन् may also refer to the velocity of flight, 'going as quick as the wind'. The most accurate measurements of flight of birds have been made from aeroplanes on birds keeping level with the machine and flying in the same direction. Thus measured by Meindertzhagen, small song-birds show an average rate of 20-37 m. per hour, crows 31-45, ducks 44-59, plovers 40-51; but these may be increased in exceptional circumstances, and an occasional rate of 100 m. an hour is quite credible.

Sanskrit literature is full of bird-lore. In the Rigveda we read यो वेद वीनां पदमन्तरिक्षे पतताम् 'Varuna, who knows the paths of birds flying through the sky'. वीनां पदं reminds us of वणिक्पथ, नौपथ and पक्षिपथ 'the bird-migration routes'.

From पत् 'to fly', there is a host of words. That they all mean a bird is not certain. Some of them definitely signify, besides a bird, flying insects. The simplest formations are पतत्, पतम, पतंग, पतंगम and पतंगिन् 'those who go flying'. पत्र masculine or neuter, besides

being used for a feather, signifies a flying creature as well. पतेर is still another word. उत्पत 'flying high or up'. There are three words which have been formed by the addition of desiderative suffixes—पित्सत्, पिपतिषु, पिपतिषत्. Here the desideratives might signify birds which are constantly on the wing.

The procedure followed in giving scientific names to birds is a simple one. If there be an ancient name of a species or subspecies, it is made the basis of the name of the genus (प्रजाति, and of the family if that be derived from the genus) to which it belongs, e. g., काक, the Common Indian House-Crow, yields काक-प्रजाति *Corvus*, the genus, and further काक-वंश *Corvidae*, the family.

In the trinomial system the Common Indian House-Crow, itself, is the subspecies *Corvus splendens splendens* सामान्य भस्मच्छवि काक. *Corvus splendens*, the species, is characterised by the ashy-brown colour of its nape, ear-coverts, head, upper back and breast. भस्म-छवि signifies the ashy-brown shade (भस्म ash, छवि colour). *Corvus splendens भस्मच्छवि काक* has four sub species: *splendens*, *zugmayeri*, *insolens* and *protegatus*. The first, being the starting point, is designated by prefixing सामान्य 'common' to भस्मच्छवि काक. The second, third and fourth sub-species are distributed over Sindh, Burma and Ceylon respectively and hence are particularised by

prefixing सिन्धु, ब्राह्म and लंका respectively. Thus—

Corvus splendens splendens सामान्य भस्मच्छवि काक

Corvus splendens zugmayeri सिन्धु भस्मच्छवि काक

Corvus splendens insolens ब्राह्म भस्मच्छवि काक

Corvus splendens protegatus लंका भस्मच्छवि काक

Each element of the Indian name is clear in connotation.

Some other species of *Corvus* काक are—

- 1 *Corvus corax* द्रोण काक (ancient word)
- 2 *Corvus levaillanti* कृष्ण काक (ancient word)
- 3 *Corvus frugilegus* संघचारी काक (संघचारी 'gregarious'—ancient word).

A species has one, two or more sub-species, of which many are found in a particular geographical zone, and hence defined by it. Thus—

Corvus levaillanti levaillanti सामान्य कृष्ण काक

Corvus levaillanti culminatus दक्षिण कृष्ण काक
(found in दक्षिण Southern India)

Corvus levaillanti intermedius हिमालय कृष्ण काक
(found in the Himalayas).

Alongside the Latin scientific names there are popular English names for every bird. The English names, at times, follow Latin closely, but often they follow a different line. They may even be binomial,

while the Latin is trinomial—(Latin) *Oriolus trailli*
trailli—(English) *Maroon Oriole*.

The English generic names are not necessarily co-extensive with Latin, *e. g.*, *Pipit* covers *Anthus* and *Oreocorys*.

After long experience we decided to provide Indian words not only for Latin names but also for popular English names. Sanskrit language and literature are rich enough to serve both.

We have been able to use ancient words by the hundred (normally a specification to this effect is registered within parentheses). While doing so we had before us the European love for their past. Edmund C. Jaeger discussing the origin of biological generic names records:

“Apparently every name of an animal used in classical Greek has been made to do service in modern nomenclature”.

He goes on further:

“And these have been modified until they form a large number of the designations in common use ...

“A large number of names comprise derivatives and compounds of the same Greek or Latin words. These names may have different forms.”

We, on our part, have not been able to use every Sanskrit name.

Sanskrit names are bearers of an imagery, all their own.

When, however, ancient names were not available, we followed the path of Pāṇini, Kātyāyana and Patañjali, and devised अन्वर्थ names, e.g.

चंचला *Fulvetta* (the birds of this genus are restless चंचल)

दीर्घ-पुच्छ *Heterophasa* (their tail पुच्छ is extraordinarily long दीर्घ)

भेक-मुख *Batracho-stomus* (the Greek word has been literally rendered into English 'Frog-mouth' and Sanskrit भेक-मुख)

मशकारि *Culici-capa* (*culicis* मशक, English 'Fly-catcher', अरि 'enemy')

वृक्ष-सर्पी *Certhia* (वृक्ष tree, सर्पी creeper)

हिम-चटक *Montifringilla* (they are all Snow हिम Finches)

सित-नयन *Zosterops* (they have a white सित ring round the eye नयन).

Modern names in North and South Indian languages have been of immense value. Such Hindi names

as were available to us have been recorded in italics along with their cognates from other North Indian languages, after the popular English names.

At the end I have great pleasure in expressing my appreciation for the loving collaboration of Shri K. N. Dave extending over more than two years. He put at my disposal his identifications of Sanskrit bird names. We have spent long time in adjusting them to the trinomial system. What we have done here is in line with the rest of our Indian nomenclature for animals and plants.

The preparation of the manuscript for the press was undertaken by my son Shri Lokesh Chandra, who also shouldered the responsibility of reading the proofs.*

PAROQUETS OR PARROTS

The Parrots of North India have been divided into two genera, one of which is represented by five and the other by a single species. They are all of a predominantly green colour and differ little in their habits. Though normally arboreal they are attracted in large flocks to ripening crops like paddy and sorghum (juar) to the great despair of the cultivator and have been regarded with birds like Buntings (अन्नदूषक) as one of the natural calamities (ईतयः) befalling a country. All the same, their brilliant plumage, quaint habits, 'sedate and knowing demeanour', and above all, their teachability to talk and perform tricks have endeared them to the people and made them one of the most favourite cage-birds of India from very ancient times.

'The Parrots rank as among the most intelligent of birds. The mere talking to which they can be trained is nothing. The wisdom of the bird, judged by this standard, is inferred from the degree of appositeness with which it utters its phrases.' (Harmsworth, Popular Science, p.2978). The European students of Indian

birdlife do not, however, credit any of the Indian species with ability to talk beyond a few words; nevertheless, Sanskrit literature attributes considerable ability to them in this respect and whole verses have been placed in their and the Hill-Maina's mouths. A couple of such examples are reproduced below:

A Parrot to his beloved Maina:

आलिङ्ग प्रतिवाचमुद्रिर सुधाकण्ठ ! क भूयो वयः ।
कोपं मुञ्च मयि प्रसीद सुभगे ! नैवं विधास्ये पुनः ॥

भावशतक

The following half-verse may well have been taught to a royal Parrot in the ordinary way, though the next two lines (not reproduced here) give it a topical setting. On the defeat of his royal patron, the bird, released from his cage, is supposed to address a painting of his master in the royal picture-gallery:

राजन् ! राजसुता न पाठयति मां देव्योऽपि तूष्णीं स्थिताः ।
कुब्जे ! भोजय मां कुमारसचिवैर्नाद्यापि किं भुज्यते ॥

काव्यप्रकाश १०।९४ ॥

If such examples had not been true a compliment like चाटु-गाथा-समुच्चारण contained in the following beautiful passage would not have been paid to a pet bird. The poet describes goddess पार्वती as playing with her pet bird:

सर्वविद्याविशेषात्मकं, चाटुगाथासमुच्चारणं,
कण्ठमूलोल्लसद्वर्णराजित्रयं, कोमलश्यामलोदारपक्षद्वयं,
तुण्डशोभातिदूरीभवत्किशुकं, तं शुकं लालयन्ती परिक्रीडसे ॥
काव्यमाला १, श्यामला-दण्डक ५ ॥

Nor would poet Kusumadeva have written:

शुकः श्लोकान् वक्तुं प्रभवति न काकः कचिदपि ।

काव्यमाला १४, दृष्टान्तकलिकाशतक पृ० ८६ ॥

Compare also:

नित्याकर्णनया शुकैः च पदं साम्नामिदं गीयते ।

नागानन्द १।१० ॥

शुक-सारिका-प्रलापन was one of the arts practised in India by professional men like the trainers of Song-finches, Canaries, Thrushes, etc. in Europe today, and no one need be surprised at the performances of exceptionally talented Parrots and Mainas recorded in Indian literature*, barring, of course, poetic exaggeration in attributing to them human intelligence and capacity to make impromptu replies or even to carry on a conversation. I have myself heard a Rose-ringed Paroquet repeat the following Hindi verse without a hitch, though the articulation was certainly not equal to that of the Maina:

* Parrots taught to repeat Lord Buddha's maxims have been described as शान्त्यशासनकुशल in हर्षचरित, ch. 8.

चित्रकूट के घाट पै भइ संतन की भीर ।
तुलसिदास चन्दन घिसै तिलक देत रघुबीर ॥

'In the midst of a gathering of saints at the waters near Chitrakoot Tulsidas prepared the sandal-paste and Ramachandra applied it to his forehead.'

Literary tradition has regarded a talking Parrot (शुक) as the mate of a talking Hill-Maina (सारिका), and it is on this supposition that वच is a Parrot and वचा a Maina, and if he is मेधावी, she is मेधाविनी which, by the way, is also the name of a most intelligent Maina in रत्नावली 2.5.6. Even Keśava, the commentator of the कौशिकसूत्र, would seem to have succumbed to this tradition, for he renders रोपणाका of Atharva Veda 1.22.4 as काष्ठसुक*, and, following him, Sāyanācarya also has translated रोपणाका (loc. cit.) as काष्ठशुकाख्यपक्षी, and again as शुका or female Parrot in his notes on तैत्तिरीय-संहिता 3.7.6, although in his commentary on ऋग्वेद 1.50.12 he correctly explains the term to mean a सारिका.

Common names for all Parrots, except the Lori-quet, are शुक and कीर, but there is reason to believe that the larger members of the group were designated as शुक and the smaller varieties like the Blossom-headed and the Slaty-headed Paroquets, which have a much softer voice

*M. Bloomfield's edition, 1890, p. 326. The insertion of सु in काष्ठसुक and the masculine gender seem to be clerical errors.

than the former, as कीर (कीर्ति अव्यक्तं शब्दं ईरयति). Names like चिरि, चिमि and चिमिक for a Parrot are also indicative of softer notes and must belong to them. This distinction still obtains in their vernacular names, e.g., सुग्गा or तोता for the large and दुइयाँ for the small Parrots in Hindi, and पोपट or राघू and कीर in Marathi. The mention of both शुक and कीर in the following extracts from (i) the स्कन्दपुराण, वेणवखण्ड and (ii) पद्मपुराण, उत्तर-खण्ड are clearly based upon the above distinction and fully support it:

(i) मयूर-कीर-गरुड-शुक-सारस-संकुलान् ।

वैकटाचल-माहात्म्य ५।५२॥

(ii) हंसैः कीरेषु पाण्डित्यं कुर्वाणैः संकुले शुकैः ।

ch. 180.21.

In literature and lexicons, however, the difference between शुक and कीर has been entirely done away with. Adnouns like त्रिकेतु, रक्त- or वक्र-तुण्ड, प्रियदर्शन, etc., apply to all Parrots but the epithet दण्डी belongs to a pet bird as 'always holding on to his perch-rod', and also, humorously, to his leading 'an ascetic and celibate life by compulsion'. Cf. कान्तां विना सीदतः said of one in सुभाषित-रत्न-भाण्डागार p. 228, verse 222. मञ्जुपाठक is true of only such birds as are able to talk.

With these preliminary remarks I proceed to a

consideration of individual names for the six species of Parrot found in North India.

1. The large Indian Paroquet (21") is marked on the wing with a large maroon-red patch. The bill is wholly red as compared with others whose lower mandible is differently coloured, and the legs and feet are of a dirty-flesh colour. Being the largest Parrot of India it is the राजशुक or शतपत्रशुक of the lexicons :

अन्यो महान् राजशुकः शतपत्रो निगद्यते—धन्वन्तरि

No Indian Parrot has red legs and the epithet रक्तपाद for one may be rendered as 'red-marked' (पादः चिह्नः अङ्कः—वैजयन्ती and विश्व) and in this sense it should belong to this bird after the conspicuous red wing-patches rather than the colour of the feet. The Blossom-headed Paroquet also has a small and inconspicuous red spot on the wing but is better named कृष्णाङ्ग शुक after its deep purplish-red head. Other poetic names for this bird are प्राज्ञ, वाग्मिन्, नृपप्रिय, etc.

2. The Rose-ringed Paroquet (16") is the commonest and by far the most numerous of all and, as it moves in large flocks, it is the one that is responsible for a major part of the total damage caused to the crops by all the Parrots put together. It is the बाहुज शुक (बाहु-ल्येन अतिशयेन जातः, very prolific?) of the lexicons but its proper name is काष्ठशुक (wild or inferior), both according

to वसन्तराज, हंसादिप्रकरण, verse 15, and केशव and सायणाचार्य as already pointed out above. Its Hindi name कठेल सुआ is an exact rendering of काष्ठ-शुक.

3. The Blossom-headed Paroquet (15") is कृष्णोत्तमाङ्ग or कृष्णाङ्ग शुक in कल्पद्रु and Monier-Williams respectively, from the colour of the head in the male. It also shares the name of कीर with the next.

4. The Slaty-headed Paroquet (16") is the पीतचञ्चु शुक of कल्पद्रु after the colour of the bill. The upper mandible is orange-yellow and the lower yellowish. In the Blossom-headed variety the lower mandible is black.

5. The Indian Red-breasted Paroquet (15") is पीतवर्ण शुक in Monier-Williams or पीतभद्र शुक (well-marked with yellow) referring to the yellow patches on its wings, and also किङ्किरात शुक (किङ्किरं रक्तवर्णत्वम् अतति—शब्दकल्पद्रुम, पीतभद्रः किङ्किरातशुके—शब्दार्थचिन्तामणि) from its red breast. A common synonymy obtains for bird and plant in this as in the case of भृङ्गराज, the Large Racket-tailed Drongo :

किङ्किरातो हेमगौरः पीतको पीतभद्रकः— भावप्रकाश, पुष्पवर्ग.
The similarity of the Hindi मदन गौर for it with हेमगौर in the above equation is also worth noting. The श्वेतशुक of the तैत्तिरीय-संहिता ५।५।१२

सरस्वते शुकः श्येतः पुरुषवाक्

is evidently this Parrot as the adjective श्येत signifies the reddish colour in the bird's plumage, and the name corresponds to किङ्किरात.

6. Lastly, the Indian Loriquet (5.5"), which is no bigger than a Sparrow, is the पत्रशुक of वसन्तराज, हंसादिप्रकरण 16, पर्णशुक of कल्पद्रु and भेदाशी of सुश्रुत, rendered as पुत्रशुक by डल्हणाचार्य. The first two names imply the colour assimilation of the bird with the green foliage of a tree. Cf. पत्रगुप्त for the Chloropsis. Salim Ali makes the following observations about these tiny birds: "On account of their small size and the wonderful oblitative effect of their colouration when clambering about among the foliage of tall trees, the birds are seldom seen except when flying across from one tree to another." The name पुत्रशुक, on the other hand, indicates its tiny size. Cf. पुत्रक and पुत्रिका for very small birds. Their habit of breaking open the hardest of nuts is reflected in the name भेदाशी. It has a short tail and no collar, and is therefore not a त्रिकेतु.

The flight of Parrots is very swift and a flock flying to or from the rich crops in the open, or hurtling through the forest, swerving gracefully to avoid trees.

and branches, is always a fine sight. A selection of verses in appreciation of their beauty at close quarters and high up on the wing should prove interesting:

तुण्डैराताम्रकुटिलैः पक्षैर्हरितकोमलैः ।

त्रिवर्णराजिभिः कण्ठैरेते मञ्जुगिरः शुकाः ॥

काव्यादर्श २।९ ॥

Parrots descending upon a paddy-field:

यत्र शालिवनोपान्ते खात्पतन्तीं शुकावलीम् ।

शालिगोप्योऽनुमन्यन्ते दधतीं तोरणश्रियम् ॥

आदिपुराण of गुणभद्र ४।६१ ॥

And pretty peasant-girls, dressed in green, driving them away:

शुकाञ्जुकच्छदच्छायै रुचिराङ्गी स्तनांशुकैः ।

छोत्कुर्वतीः कलकाणं सोऽपश्यच्छालिगोपिकाः ॥

Ibid. 35, 36.

A Yakṣa describes to Arjuna a flight of Parrots, many carrying golden ears of paddy in their bills:

मुखेरसौ विद्रुमभङ्गलोहितेः

शिखाः पिशङ्गीः कलमस्य बिभ्रती ।

शुकावलिर्व्यक्तशिरीषकोमला

धनुश्रियं गोत्रभिदोऽनुगच्छति ॥

किरातार्जुनीय ४।३६ ॥

Poet Māgha also presents a similar picture:

हरितपत्रमयीव मरुद्गणैः
स्रगवनद्धमनोरमपल्लवा ।
मधुरिपोरभिताम्रमुखी मुदं
दिवि तता विततान शुकावलिः ॥

शिशुपालवध ६।५३॥
